*% detected as AI

AI detection includes the possibility of false positives. Although some text in this submission is likely AI generated, scores below the 20% threshold are not surfaced because they have a higher likelihood of false positives.

Caution: Review required.

It is essential to understand the limitations of AI detection before making decisions about a student's work. We encourage you to learn more about Turnitin's AI detection capabilities before using the tool.

Disclaimer
Our AI writing assessment is designed to help educators identify text that might be prepared by a generative AI tool. Our AI writing assessment may not always be accurate (i.e., our AI models may produce either false positive results or false negative results), so it should not be used as the sole basis for adverse actions against a student. It takes further scrutiny and human judgment in conjunction with an organization's application of its specific academic policies to determine whether any academic misconduct has occurred.

Frequently Asked Questions

How should I interpret Turnitin's AI writing percentage and false positives?
The percentage shown in the AI writing report is the amount of qualifying text within the submission that Turnitin's AI writing detection model determines was either likely AI-generated text from a large-language model or likely AI-generated text that was likely revised using an AI paraphrase tool or word spinner.

False positives (incorrectly flagging human-written text as AI-generated) are a possibility in AI models.

AI detection scores under 20%, which we do not surface in new reports, have a higher likelihood of false positives. To reduce the likelihood of misinterpretation, no score or highlights are attributed and are indicated with an asterisk in the report (*%).

The AI writing percentage should not be the sole basis to determine whether misconduct has occurred. The reviewer/instructor should use the percentage as a means to start a formative conversation with their student and/or use it to examine the submitted assignment in accordance with their school's policies.

What does 'qualifying text' mean?
Our model only processes qualifying text in the form of long-form writing. Long-form writing means individual sentences contained in paragraphs that make up a longer piece of written work, such as an essay, a dissertation, or an article, etc. Qualifying text that has been determined to be likely AI-generated will be highlighted in cyan in the submission, and likely AI-generated and then likely AI-paraphrased will be highlighted purple.

Non-qualifying text, such as bullet points, annotated bibliographies, etc., will not be processed and can create disparity between the submission highlights and the percentage shown.

Smart Helpdesk Ticketing Solution For IT Services

Abstract- This article focuses on how Organizations today are reliant on IT services as part of their everyday operations. Unfortunately, many legacy/helpdesk systems are operating via manual processes, long response times, and poorly tracked ticketing processes, which all lead to decreased productivity and lower customer satisfaction. This research includes the development of a 'Smart Helpdesk Ticket System for IT Services' to overcome these issues. This will be developed as a web-based solution employing Python, Flask, and SQL for efficient data management and system performance. This website will allow users to submit support requests easily, track those requests, and receive updates regarding the status of their support requests in a timely manner. Administrators and Technician will be able to manage, assign and prioritize requests in an efficient and organized fashion. Another aspect of the overall design of this system will include an NLP-based chatbot as part of the system to answer common questions and assist with the creation of support tickets, which will reduce response times and relieve some of the burden on IT support teams. Ultimately, this means that there will be a central communication tool to support the improvement of communication between users and IT; provide greater transparency for service delivery; improve reliability and intelligence of the IT Support Environment through modern web technologies and intelligent automation; and improve the speed by which incidents are found and resolved. This solution will contribute to improved IT service management and will create a better user experience.

Keywords: Smart Helpdesk Ticketing System (Software), Helpdesk Ticketing Management, IT Service Management, Web-Based Applications (software), Python Flask (Programming Language), SQL Database (Data Storage), NLP Chatbot, Automation, IT Support Ticket System, Service Efficiency.

I. INTRODUCTION

Organizations in today's digital environment depend on IT services for many important functions, such as supporting the daily operations of the organization, communicating, and managing their data. As their reliance upon technology grows, an effective IT Service Management (ITSM) system becomes even more necessary. A major component of any ITSM system is its helpdesk ticketing system; this is where users report and track their technical problems and IT teams resolve them.

Many older helpdesk systems continue to have problems with delayed responses, poor prioritization of tickets, little transparency, little automation, and inefficient communication between users and IT teams. Numerous studies have attempted to address these problems by developing web-based ticketing systems, creating an Agile or Rapid Applications Development (RAD) methodology for ticket management, integrating AI-enabled chatbots into ticket submission/communication/automated resolution processes, applying gamification techniques to encourage users to submit tickets as well as for IT teams to resolve them quickly, and using blockchain-based technologies to securely manage tickets during their lifecycle.

Research has confirmed that web-based ticketing systems provide improved documentation and accessibility of information and that both the use of automation and the integration of AI-based chatbots reduce the time it takes to resolve user requests significantly. Additionally, research demonstrates that creating user-centered UI/UX designs will result in improved usability when using the helpdesk ticketing system and that implementing motivational strategies will improve IT teams' ability to provide quality service to users.

Although these advances have improved the way both users and IT teams work together to resolve technical issues, there remains an opportunity to create an all-inclusive Smart Helpdesk System that can integrate all of the aforementioned

components into a single, effective platform for automating ticket resolution, providing intelligent assistance to users, maintaining a complete record of each ticket's lifecycle along with performance monitoring functionality.

This project mainly involves:

1. Build a Web-Based Help Desk Ticketing System.
2. Integrate an NLP-Based Chatbot for Intelligent Automation.
3. Improve Service Efficiency through Intelligent Ticket Management and Monitoring.

II. LITERATURE REVIEW

Helpdesk ticketing solutions are very important in the management and control of the IT service requests, incidents management, and enhancement of workflow in the organization. The helpdesk systems have been proposed to be improved through the years by different approaches based on web technologies, agile development, the integration of AI, and automation techniques.

Chanchad et al. [1] turned out to be the pioneering Helpdesk Ticketing System with emphasis on the systematic complaint management and the systematic ticket allocation. Their activity focused on the use of digital monitoring of problems, classification of requests, and administrative observation to minimize the work of the manualist. The paper gives a fundamental architectural knowledge on ticket lifecycle management.

Simanjuntak et al. [2] created a web-based helpdesk ticketing application of PT Pertamina EP in the Agile methodology. Their study established that incremental growth enhances system flexibility and customer contentment. Similarly, the group of researchers led by Putra et al. [3] developed a RAD-based (Rapid Application Development) system of web-based service desk systems that emphasize fast speed of application deployment along with developing an application with a high level of usability based on the users' feedback. The research conducted by these authors shows that agile development principles are very beneficial for improving the responsiveness and usability of an information technology system.

Another paper authored by Herdiansyah et al. [4] focused on web-based service desk information systems for structured work flow management and performance tracking at PT Semen Baturaja. The authors demonstrated reduced turnaround times and improved ticket resolution times in the service desk by implementing their information system solution. An example of an information system solution that focuses on ticketing, which was provided by Rachmawati et al. [12], used the university's service desk operations to develop a systematic Ticketing System and an efficient interaction between university students and information technology personnel in resolving service requests.

Another important aspect of helpdesk systems is optimization of UI/UX. Hartina et al. [6] used Design Thinking as a method of enhancing the UI/UX of a helpdesk reporting feature. Their results show that user-centered design has a significant effect on user satisfaction and system usability.

The latest progress incorporates Artificial Intelligence into the work of the helpdesk. Sasmita et al. [7] created an AI-based chatbot with the Rasa framework to enhance the services of the government helpdesk. They showed that automation of chatbots shortens response time and makes the services more efficient.

Equally, Mehrab [8] examined those AI-driven automation and chatbots to enhance the efficiency of the IT helpdesk with a special focus on intelligent classification of tickets and automated replies.

Organizational, as well as motivational aspects, has been examined. Tanuraharja and Wang [9] examined the motivation of an IT team in the application of IT help desk systems and found that the usability of the system and management support are two important factors in adoption and productivity.

There are also emerging technologies that have been suggested like blockchain. Sharma [10] proposed a smart ticketing system based on blockchain to increase the levels of transparency, security and data integrity in the ticket management systems. Also, Licina et al. [5] studied the optimization of helpdesk ticketing services with the inclusion of Discord community platforms, which proved to be more effective in terms of collaborative support mechanisms.

Khalid and Alosaimi [11] offered detailed IT support and helpdesk optimization strategies as they are aimed at the promotion of user experience, operational efficiency, and compliance to the service-level agreement (SLA).

Based on the literature review, it is clear that conventional web-based helpdesk systems have been developed to AI-based, automated, and user-centric systems. Nevertheless, the necessary element is the integrated solution that would incorporate the structured ticket management, AI-driven automation, current principles of UI/UX, and scaled architecture specifically oriented towards the IT service settings. Thus, the Smart Helpdesk Ticketing Solution of IT Services is proposed to fill these gaps with the use of intelligent automation, effective workflow management, and user-oriented system design.

III. METHODOLOGY

The Smart Helpdesk Ticketing System has been developed by using a modular and structured methodology to help IT services improve their service provision. The system is web-based and has a client/server architecture that allows for improved access, scalability, and centralized control.

The system has integrated multiple components into a single application, including user interface, administration, data management, and intelligent assistance.

In a modular design, there is a separation of the functionality of each component and they work independently of each other; however, they communicate with each other through a centralized database.

A. DATA MANAGEMENT AND WORKFLOW:

All users' user information, ticket information, priority of tickets, ticket status changes, etc. is stored and managed through a relational database. Each ticket has a unique reference number which allows for complete tracking of each ticket through its entire lifecycle.

Requests for IT services are identified, managed and tracked in an organized fashion through the use of a defined ticket workflow which includes steps of creating the ticket; assigning the ticket; status changes to the ticket (open, in-progress, resolved or closed) until the ticket finally closes out and the service request is completed. Using a structured ticket lifecycle allows for

improved transparency, accountability and efficiency for request handling within IT services.

B. FUNCTIONAL & IMPLEMENTATION OF THE SYSTEM

Users are able to create and track tickets, administrators are able to manage and prioritize requests, and technicians are responsible for resolving tickets. It uses Python with the Flask framework to process the back-end of the application, along with HTML, CSS, and Javascript for front-end development within a modular development method that enhances the system's scalability, flexibility and maintainability.

C. INTELLIGENT AUTOMATION & EVALUATION

To enhance operations, automated responses through an NLP-based chatbot are incorporated into the system to provide automated responses to frequently asked questions and assist users with ticket creation. This enables the user to complete tickets using their computer instead of manually creating them. Furthermore, it decreases manual efforts and provides an overall improvement to service transparency. The system will undergo three separate types of testing; unit testing, integration testing and functional testing to ensure both reliability and correctness. Lastly, the system's performance will be assessed using the average response time, ticket handling efficiency, decrease in manual effort, and need for increased service transparency.

IV. IMPLEMENTATION AND EVALUATION

A. SYSTEM IMPLEMENTATION

The Smart Helpdesk Ticketing Solution was introduced as an IT service management web-based application aimed at automation of tickets handling and enhancement of support transparencyA modularized architecture separates user activity, administrative oversight, and analytical review of the entire application suite.

The User Module provides functionality for an employee to create a support ticket. Each ticket contains a description of the problem, the type of problem (software or network), and an assigned priority level. Every ticket has an individual identification number and a time stamp. Each user has a dashboard from which they can track live updates of their various tickets.

The Admin Module provides centralized control of all support tickets submitted. Administrators can change the priority of the ticket, assign an appropriate status (open, in-progress, resolved) to each ticket, and determine whether or not the overall system is performing properly. The life cycle of a ticket is designed to allow all involved parties to track the systematic resolution of IT related issues throughout the lifecycle of the IT issue.

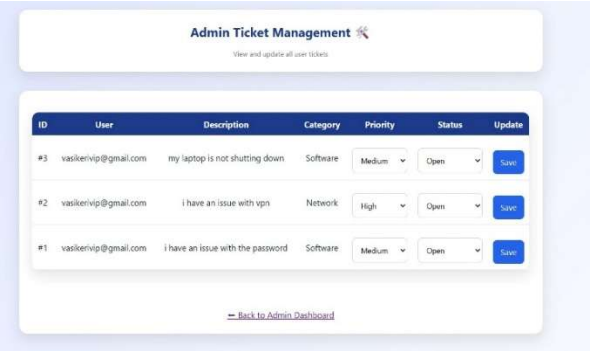

Fig 1: Admin Ticket Management Interface

The Dashboard Module displays summary statistics that include: open ticket count, in-progress ticket count, number of cases that have been resolved, number of high priority cases. The Dashboard module also provides an overview of item allocations by category, which permits administrators to identify operational bottlenecks.

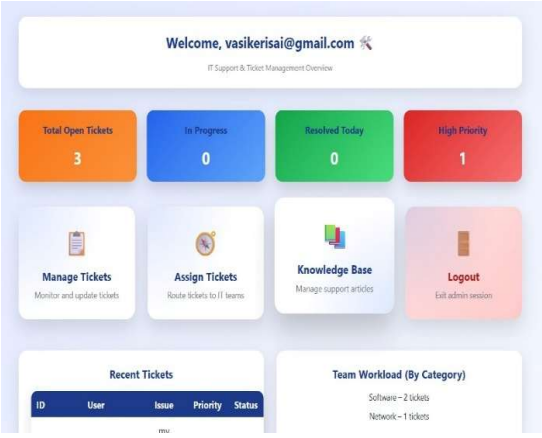

Fig 2: Admin Dashboard Overview

Integrity and consistency of all data transactions is ensured via secure backend services and placement of data within a structured database. The system enables real-time changes in status to be displayed concurrently to users through their user interface and to administrators through the administrator interface.

B. PERFORMANCE EVALUATION

The functional validation and operational performance evaluation of the system under evaluation were performed using both functional validation techniques to test its core elements and operational performance assessments to test the operation of the system throughout the lifecycle of a ticket. Several functional tests were conducted to verify basic functionality such as ticket submission, modification of priority and status updates, as well as maintaining appropriate calculation of Dashboard metrics. The ticket lifecycle transitions occurred without error in all areas of functionality tested.

The performance results from the operational performance assessment provided information regarding the speed of the system's operational environment while performing ticket operations. The speed of ticket submissions, and ticket status updates, provided sufficient response times for users wishing to complete these tasks in a timely manner and have responsive conversations with the administrator of the system.

In addition, the dashboard analytics provide a better view of the IT workload by providing insight into the distribution of high-priority issues on the dashboard. The proposed solution is considered to be significantly more transparent and structured by allowing for tracking of documented records, rather than using manual or email systems to provide customers with support.

When users submit tickets through the use of the Ticket Submission Interface they will have an opportunity to provide a brief and concise description of their problem. During the testing phase of the Ticketing System, all submitted tickets were recorded in real-time with no waiting periods for the users to receive responses to their submissions. Users will also benefit from an intuitive design of this interface that requires minimal effort to use in order to complete the ticket submission process;

therefore allowing for a more efficient and effective method of performing support functions and tracking support interactions for continued improvement.

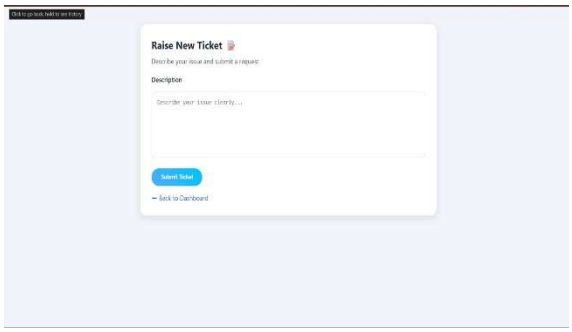

Fig 3: Interface for Raising New Support Tickets

The implementation, in general, is proven to work reliably, provide better ticket traceability, and provide effective IT support management which can be used in an institutional or organizational setting.

V. RESULTS AND DISCUSSION

The Smart Helpdesk Ticketing System is far superior to older, manual, and email-based Support systems. The Smart Helpdesk Ticketing System was tested using multiple Functional and operational test cases, to determine performance, usability, and efficiency.

It is evident that the Smart Helpdesk Ticketing System allows for ease of ticket submission, as well as real-time tracking. The Smart Helpdesk Ticketing System provides each request with a defined structure throughout each phase of a ticket's lifecycle. Tickets are recorded, assigned, and resolved without data loss. Tickets can be managed and monitored via an Administrator Dashboard. The Administrator Dashboard provides a complete overview of the activity occurring within the Smart Helpdesk Ticketing System.

The integration of an NLP-based chatbot allows the user to have their frequently asked questions answered by the bot and also assists the user in creating a ticket, resulting in a reduction of time being spent on IT support staff completing common issues. In addition, Dashboard Analytics assist in decision making by giving Administrators insight into ticket distribution, workload balance, and high priority issues.

Ticketing System Dashboard(s) are meant to enable users to have a clear overview/understanding of how many tickets exist overall (total of both open/in-progress/closed tickets) as well as other metrics regarding their ticket management activities. In addition, this will also provide users with immediate access to critical functions associated with ticketing such as creating tickets, tracking tickets, receiving assistance via chatbot, accessing the Knowledge Base, along with providing users access to the most recent tickets and new ticket-related announcements to improve transparency and increase user knowledge, thereby providing a greater ability for users to make informed decisions quickly and more efficiently within the system.

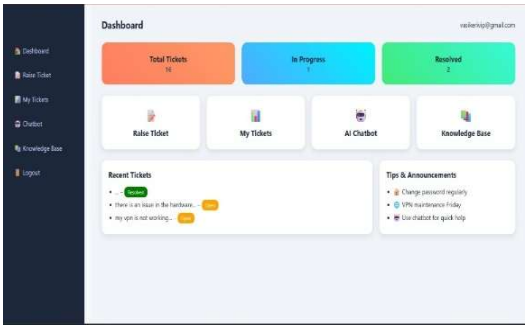

Fig 4: User Dasboard

The Smart Helpdesk Ticketing System enables users to submit and retrieve support request tickets quickly. Due to the modular design of the system, tickets consistently receive quality service no matter how many users are submitting support requests at the same time. Once again, Smart Helpdesk Ticketing Systems outperform traditional support systems in terms of service efficiency, transparency, and administrative load.

VI. CONCLUSION AND FUTURE WORK

Smart Helpdesk Ticketing provides an easy way to submit and extract support request tickets for use in the support process. Because of the modular design of this system, all submitted tickets will be handled with quality regardless of how many tickets are submitted simultaneously. Again, Smart Helpdesk Ticketing Systems have demonstrated superior performance to traditional support systems in terms of service effectiveness, visibility, and administrative burden.

Organizations can build better communication between users and IT Support Teams by using this Smart Helpdesk, improve ticket traceability throughout lifecycle, better manage IT resources via real-time central visibility into all tickets being worked on, who is working on them; and enhance user experience through an intelligent chatbot, providing instant assistance and significantly reducing the amount of work for IT Support Staff.

The future enhancements of the Smart Helpdesk system include but are not limited to the integration of advanced AI and machine learning capabilities, which will facilitate superior classification of help desk tickets and improving prioritizing and predicting tickets when they are created and offering automated suggested resolutions for tickets. Other future enhancements include, but are not limited to, the addition of automatic notifications to users, multiple language support for the chat bots, and analytics that predict potential requests for assistance.Lastly, the Smart Helpdesk will have the capability to be deployed via the cloud and integrate with other enterprise IT Service Management Tools to enhance the overall availability of the Smart Helpdesk.
